## Interfacing LCD with Pt-51 kit

EE319: Microprocessor and Microcontroller Laboratory

Department of Electrical Engineering Indian Institute of Technology Dharwad

### Overview

Introduction
JHD 162A LCD Display

Hardware and Software Interfacing

Configuring the LCD

Displaying Text on the LCD

Lab Assignment

Introduction

### JHD 162A LCD Display

- The display provided with the Pt51 kit (JHD 162A)
- JHD 162A can display up to 16 characters per line in two lines (hence its name – 16 2A).

Figure: JHD 162A Display

- Controlling the LCD display is done by sending **commands** and **data** from the micro-controller on Pt51 (AT 89C5131A) to the micro-controller on the display (HD44780U).
- HD44780U has a local memory which stores the characters to display and a programmable memory which stores fonts.

#### LCD connection to Pt-51 kit

Introduction

# Hardware and Software Interfacing

#### Hardware

- Three control lines from *Port P0* to HD44780
  - P0.0 Register Select (RS)
  - P0.1 Read or Write (RW)
  - P0.2 Enable (EN)
- RS decides whether a **command** or **data** is sent
  - RS = 0 for command transfer
  - RS = 1 for data transfer
- RW decides whether a read or write operation is desired
  - RW = 0 for write operation
  - RW = 1 for read operation

- EN provides hand shake for command/data transfer
  - EN = 0 at start of command/data transfer
  - EN = 1 to look for command/data transfer and set back to EN = 0
  - HD44780 acts on the command/data only when EN has a downward transition.
- 8 lines from Port P2 to HD44780 for data

#### Software

• Following equates can be defined in program for control and data lines:

RS EQU PO.0

RW EQU PO.1

EN EQU PO.2

Data EQU P2

```
LCD_data equ P2 ;LCD Data port
LCD_rs equ P0.0 ;LCD Register Select
LCD_rw equ P0.1 ;LCD Read/Write
LCD_en equ P0.2 ;LCD Enable
```

```
/* @section I N C L U D E S */
#include <AT89C513xA.h>
#define LCD_data P2
#define LCD_rs P0_0
#define LCD_rw P0_1
#define LCD_en P0_2

/*Function Declarations*/
void LCD_Init();
void LCD_DataWrite(unsigned char dat);
void LCD_CmdWrite(unsigned char cmd);
void sdelay(unsigned int delay);
```

Figure: Port definitions in ASM and C language

- The position of the first non-zero bit (from MSB) determines what kind of command.
- If DB7 = 1, it is the display data RAM address set command. The rest of the bits specify the address in the display RAM from where the next read/write will be carried out.
- If DB6 = 1 is the first non zero bit, it is the *character generator address set command*. The remaining bits will be character generator RAM address.
- If DB7, DB6 are 0 and DB5 = 1, it is the function set command. Then, DB4 specifies the number of data bits (NDB) used by the interface, DB3 gives the number of display lines (NDL) in the display and DB2 picks the font (F).
- If DB4 is the first non zero bit, it is the *shift command*. DB3 gives whether the display or the cursor will be shifted, while DB2 signifies whether a right or left shift is desired.

0000

- If DB3 is the first non zero bit, it is the display switch command. Then, value at DB2 determines if the whole display will be turned on/off (D), DB1 is for turning the cursor on/off (C), while DB0 turns blinking of the cursor on or off (B).
- If DB2 is the first non-zero bit, it is the input set command. Here, DB1 is interpreted as auto increment/decrement mode of cursor position (I/D) while DB0 signifies whether the display should shift (S) after entering the new character by one position.
- If DB1 is the first non-zero bit, it returns the cursor to the first position.
- If DB0 is the only non-zero bit, it clears the screen.

## Configuring the LCD

#### Step 1: Function set command

- To configure the LCD, we need to send a function set command first.
- Function command sets interface data length or the number of data bits (NDB), number of display line (NDL), and character font (F).
- Without this command, the display will not know whether to interpret the rest of the communication as 8 bit data or 4 bit data.
- Function set has the following format:

DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	1	NDB	NDL	F	-	-

- DB 765 = 001 signifies that it is a function set command.
- NDB is 1 for 8 bit data interface and 0 for 4 bit interface, NL is 1 for a 2 line display, 0 for a single line display and F is 1 for a  $5 \times 10$  font and 0 for a  $5 \times 7$  font.
- For a 2 line display with  $5 \times 7$  font on an 8 bit interface, we need to send 00111000 = 38H.

# Configuring the LCD (cont..)

#### Step 2: Display switch command

- The LCD display is turned ON/OFF by sending the display switch command.
- Display switch command sets on/off of all display (D), cursor on/off (C), and blink of cursor on/off (B).
- Display switch has the following format:

	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
Ì	0	0	0	0	1	D	С	В

- D is 0 for display OFF and 1 for display ON, C is 0 for cursor OFF and 1 for cursor ON and B is 0 for cursor blink OFF and 1 for cursor blink ON.
- To turn on the display with a cursor which is not blinking, we send 00001110 or 0EH.

### Step 5. Input set command

- Finally, program the display in such a way that every time we send a character, the cursor automatically shifts to the right by one position.
- Here I/D stands for auto increment/decrement of cursor position while S is for shift control. These operations are performed during data read/write.
- This command has the following format:

DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	0	0	0	1	I/D	S

• For just incrementing the cursor position, we send 00000110 or 06H.

- Thus, configuring/initializing of the display involves sending 38H, 0EH and 06H to the display to set it to the mode described above.
- Each command should be sent after ensuring through a status read that the display  $\mu C$  is no more busy.

#### Step 4: Clear screen command (optional)

• One may optionally clear the screen after this by sending a clear screen command 00000001 or 01H.

### LCD initilization (in ASM)

```
:-----LCD Initialisation routine-----
lcd init:
           A,#38H ;Function set: 2 Line, 8-bit, 5x7 dots
       acall lcd command
            A,#0CH ;Display on, Curson off
       acall lcd command
           A,#01H ;Clear LCD
       acall lcd command
           A,#06H ;Entry mode, auto increment with no shift
       MOV
       acall lcd command
       ret
                        :Return from routine
```

### Command writing subroutine (in ASM)

```
:-----command sending routine-----
lcd command:
            LCD data.A
                         :Move the command to LCD port
       MOV
       clr
                         :Selected command register
            LCD rs
       clr
            LCD rw
                         ;We are writing in instruction register
       setb
            LCD en
                         :Enable H->L
              acall delav
       clr
            LCD en
              acall delay
       ret
```

```
void LCD Init()
  sdelay(100);
  LCD CmdWrite(0x38):
  LCD CmdWrite(0x0C);
  LCD CmdWrite(0x01);
  LCD CmdWrite(0x06):
```

```
/* LCD 2lines, 5*7 matrix*/
/* Display on, Curson off*/
/* Clear the LCD*/
/* Entry mode, auto increment with no shift*/
```

### Command writing subroutine (in C)

- After initialization, for displaying text, write each character to the display in data mode.
- Before sending each character, one must ensure that:
  - LCD is not busy
  - Position the text at a particular place in the display
    - To position text/cursor, the data address must be set accordingly (as a command)
    - The sixteen characters in the first line reside at data address 80H to 8FH.
    - Addresses for the second line span the address range C0H to CFH.
- Send each character to be shown on LCD as data

#### Writing data (in ASM)

```
:------data sending routine-----
lcd senddata:
            a, #'p'
       MOV
            LCD data, a ; Move the command to LCD port
       MOV
       setb
            LCD rs :Selected data register
       clr
            LCD rw ;We are writing
       setb
            LCD en
                        :Enable H->L
             acall delav
       clr
            LCD en
       acall delay
             acall delay
                        ;Return from busy routine
       ret
```

### Writing data (in C)

## Main Program

#### Main program section in ASM and C

```
ORG BBBBH
limp start
org 200h
start:
        mov P2.#00h
        acall delay ;initial delay for lcd power up
        acall delay
        acall lcd init
                           :initialise LCD
        acall delay
        acall delay
        acall delay
        mov a,#085h
                                ;Put cursor on first row,5 column. For second row third column, OC3h
        acall lcd command
                                :send command to LCD
        acall delay
        acall lcd senddata
                                  :call text strings sending routine
        acall delay
here: simp here
                                       :stav here
```

#### Additional subroutines

### Delay subroutine in ASM and C

# Lab Assignment

#### Problem Statement:

- 1. One line display: Verify the sample program provided, both in C and ASM, by displaying
  - a particular character on first line at the right end.
  - a particular integer on left end of the second line.
- 2. Two line display: Modify the sample program to display your name and today's date in two lines of lcd display (in both C and ASM). Eg:'XYZ' on first line and '10 OCT 2022' on second line. Make sure to align the text to the middle of the display.
